AN EXACT TRANSFORMATION FROM GEOCENTRIC TO GEODETIC COORDINATES FOR NONZERO ALTITUDES

David R. Hedgley, Jr. Flight Research Center

INTRODUCTION

In space position measurement systems, it is often necessary to transform geocentric to geodetic coordinates. Consequently, it is important to have an exact closed-form solution for the transformation that is free of embedded singularities. An exact solution is particularly important for determining missile positions. All the previous work in this area falls into two categories: formulas that are mathematically exact but involve equations that become unstable in the neighborhood of their singularities, and formulas that are approximations that may or may not have inherent singularities. References 1 and 2 are of the former type, and references 3 to 5 are of the latter.

Although some of these methods are adequate under some conditions, they have limitations under certain circumstances. This paper presents an exact closed-form solution for the transformation that is free of singularities. The solution permits the evaluation of any of the existing methods under any conditions and should serve as a primary standard.

The appendix contains computer subroutines that implement the ideas that follow and examples of input and output data.

SYMBOLS

Parenthetical symbols are computer identifiers for variables.

a (A) major axis of ellipsoidb (B) minor axis of ellipsoid

d the distance from any point in space to the ellipsoid

 $d_{x} = x_0 - x_2$

 d_{y} $= y_0 - y_2$ d_z $= z_0 - z_2$ e (E) eccentricity f (F) flattening factor f(x,y,z)general function to be minimized restraint imposed on ffunction which is composite of functions f and gHaltitude normal to the ellipsoid h (ALT) h_s (ALTS) altitude computed from distance formula any point in space p_0 the point on the ellipsoid that is the minimum distance from the p_2 point p_0 percentage of error in d percentage of error in d_{y} percentage of error in d_z X coordinate axis that intercepts the Greenwich meridian coordinates of any point on the ellipsoid x, y, zcoordinates of p_0 x_0, y_0, z_0 (X0,Y0,Z0)coordinates of p_2 x_2, y_2, z_2 (X2,Y2,Z2)coordinate axis that is in a direction normal to the plane deter-Y mined by the intersection of X and Z \boldsymbol{Z} coordinate axis that intercepts the poles

α (V) arbitrary real constant to be determined

 ϵ error in α

 λ_e (ALONG) longitude east

 $\lambda_{_{\hspace{-.1em}W}}$ (ALONG) longitude west

φ (ALAT) geodetic latitude

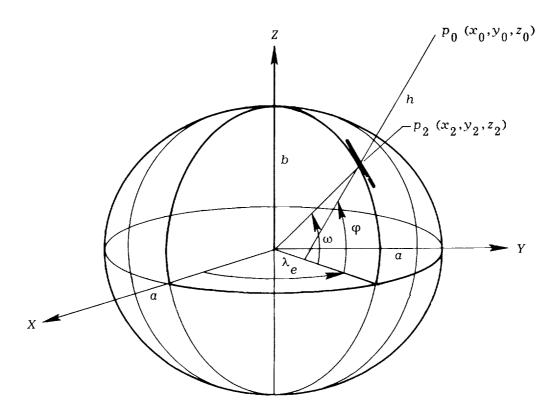

ω geocentric latitude

ANALYTICAL FORMULATION

Let a model of the earth be an ellipsoid given by the following equation (ref. 6):

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} + \frac{z^2}{b^2} = 1 \tag{1}$$

where a>b. In addition, let p_0 (x_0,y_0,z_0) be any point above the ellipsoid, as shown in the sketch below.

The line perpendicular to the surface of the ellipsoid from p_0 is the altitude of p_0 above the ellipsoid and hence is the shortest distance from p_0 to that surface (eq. (1)).

Therefore, by minimizing the distance from p_0 to the surface of the ellipsoid, it is possible to acquire the coordinates $(x_2, y_2, \text{ and } z_2)$ of the point on the surface that cause the distance defined by

$$d = \left[\left(x - x_0 \right)^2 + \left(y - y_0 \right)^2 + \left(z - z_0 \right)^2 \right]^{1/2}$$
 (2)

to be minimum.

The Lagrange multiplier method (ref. 7) is used to implement this minimization where

$$f(x,y,z) = (x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2$$

and

$$g(x,y,z) = \frac{x^2}{a^2} + \frac{y^2}{a^2} + \frac{z^2}{b^2} - 1$$

Then

$$H(x,y,z,\alpha) = (x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2 - \alpha \left(\frac{x^2}{a^2} + \frac{y^2}{a^2} + \frac{z^2}{b^2} - 1\right)$$

If partial derivatives are taken in turn and each is equated to zero, the following equations result:

$$\frac{\partial H}{\partial x} = 2\left(x - x_0\right) - \frac{\alpha 2x}{a^2} = 0 \text{ or } x = x_0/\left(1 - \alpha/a^2\right)$$
(3)

$$\frac{\partial H}{\partial y} = 2\left(y - y_0\right) - \frac{\alpha 2y}{a^2} = 0 \text{ or } y = y_0/\left(1 - \alpha/a^2\right)$$
 (4)

$$\frac{\partial H}{\partial z} = 2\left(z - z_0\right) - \frac{\alpha 2z}{b^2} = 0 \text{ or } z = z_0/\left(1 - \alpha/b^2\right)$$
 (5)

$$\frac{\partial H}{\partial \alpha} = -\frac{x^2}{a^2} - \frac{y^2}{a^2} - \frac{z^2}{b^2} + 1 = 0 \tag{6}$$

Equations (3) to (5) can be substituted into equation (6) as follows:

$$-\left[x_0/\left(1-\alpha/a^2\right)\right]^2/a^2 - \left[y_0/\left(1-\alpha/a^2\right)\right]^2/a^2 - \left[z_0/\left(1-\alpha/b^2\right)\right]^2/b^2 + 1 = 0$$

or

$$-x_0^2 \left(b^2 - 2\alpha + \alpha^2/b^2\right) - y_0^2 \left(b^2 - 2\alpha + \alpha^2/b^2\right) - z_0^2 \left(\alpha^2 - 2\alpha + \alpha^2/a^2\right) + \left(\alpha^2 - 2\alpha - \alpha^2/a^2\right) \left(b^2 - 2\alpha + \alpha^2/b^2\right) = 0$$

Simplifying and collecting,

$$(1/a^{2}b^{2})\alpha^{4} - 2(1/a^{2} + 1/b^{2})\alpha^{3} + (4 + a^{2}/b^{2} + x_{0}^{2}/b^{2} - y_{0}^{2}/b^{2} - z_{0}^{2}/a^{2})\alpha^{2}$$

$$+ 2(x_{0}^{2} + y_{0}^{2} + z_{0}^{2} - a^{2} - b^{2})\alpha + a^{2}b^{2} - x_{0}^{2}b^{2} - y_{0}^{2}b^{2} - z_{0}^{2}a^{2} = 0$$

$$(7)$$

This is a quartic equation in α and can be solved in closed form (ref. 8). The proper solution can be determined if the solution is restricted to the real zeros of equation (7) and that zero of equation (7) is chosen that causes d to be smallest. The appropriate solution of this quartic has no singularities. That is, α does not approach plus or minus infinity, because that would imply from equations (3) to (5) that x_2 , y_2 , and z_2 equal zero. Equations (3) to (5) do not become unstable, because the statement $\alpha = a^2$ or $\alpha = b^2$ implies that x_2 , y_2 , or z_2 approaches infinity. Since altitude is nonzero, α does not equal zero.

Let α_0 be that zero that satisfies the quartic equation. Then, from equations (3) to (5),

$$x_2 = x_0 / (1 - \alpha_0 / a^2) = x_0 a^2 / (a^2 - \alpha_0)$$
 (8)

$$y_2 = y_0 / (1 - \alpha_0 / a^2) = y_0 a^2 / (a^2 - \alpha_0)$$
 (9)

$$z_2 = z_0 / (1 - \alpha_0 / b^2) = z_0 b^2 / (b^2 - \alpha_0)$$
 (10)

$$h_s = \left[\left(x_2 - x_0 \right)^2 + \left(y_2 - y_0 \right)^2 + \left(z_2 - z_0 \right)^2 \right]^{1/2}$$
 (11)

$$\varphi = \sin^{-1}(z_0 - z_2)/h_s \tag{12}$$

$$\lambda_e = \tan^{-1}(y_2/x_2) = \tan^{-1}(y_0/x_0) = -\lambda_w$$
 (13)

Although the foregoing formulas are mathematically exact, for computational reasons it is usually advantageous to normalize all distances, because this minimizes errors due to rounding off. However, errors due to rounding off are still possible. To circumvent this problem for altitudes not near zero, consider the following error analysis with respect to the computation of $h_{_{\rm S}}$, λ , and ϕ .

Let ϵ be a small error introduced in the computation of the zero of the quartic. In addition, let $d_z = z_0 - z_2 = -z_0 \alpha_0 / (b^2 - \alpha_0)$. Then the error in d_z is introduced by α_0 only, because a, b, x_0 , y_0 , and z_0 are all exact. It is easy to show that the percentage of error, t_z , of d_z is as follows:

$$t_z = -1 + \left(1 + \varepsilon/\alpha_0\right) \left[\left(b^2 - \alpha_0\right) / \left(b^2 - \alpha_0 - \varepsilon\right) \right]$$

From equation (10), $b^2 - \alpha_0 > b^2$. Therefore $\left|b^2 - \alpha_0\right| > \left|\alpha_0\right| > \left|\epsilon\right|$, and since ϵ is small, $\left(b^2 - \alpha_0\right)/\left(b^2 - \alpha_0 - \epsilon\right) \approx 1$. Therefore $t_z \approx \epsilon/\alpha_0$. Similarly, $t_x, t_y \approx \epsilon/\alpha_0$.

Since equation (12) involves the ratio of two numbers with virtually equal percentages of error, latitude is undisturbed by a small error in the computation of α_0 due to rounding off.

As noted above, this analysis is valid only if the altitude does not approach zero; otherwise α_0 approaches zero and the value $|\epsilon/\alpha_0|$ may approach infinity. The instability of $|\epsilon/\alpha_0|$ suggests that equation (12) may become unstable under these conditions.

This final problem can be resolved. If p_2 (x_2, y_2, z_2) is the point on the ellipsoid that intersects the normal drawn from p_0 (x_0, y_0, z_0) , the following equation (ref. 6) may be used:

$$\varphi = \tan^{-1} \left[\tan \omega / \left(1 - e^2 \right) \right] \tag{14}$$

where $\tan \omega = z_2/\left(x_2^2 + y_2^2\right)^{1/2}$. From these relationships, ϕ may be determined immediately. The error, if any, in $\tan \omega$ introduced by the computational round-off error in α_0 is inconsequential, because it can easily be shown that the percentage of error in x_2 , y_2 , and z_2 is virtually zero. In fact, the percentage of error in z_2 and x_2 or y_2 is given by $\left(b^2 - \alpha_0\right)/\left(b^2 - \alpha_0 - \varepsilon\right) - 1$ and $\left(a^2 - \alpha_0\right)/\left(a^2 - \alpha_0 - \varepsilon\right) - 1$, respectively. Since ε is small for any value of α_0 , the quantities

 $(b^2 - \alpha_0)/(b^2 - \alpha_0 - \epsilon)$ and $(a^2 - \alpha_0)/(a^2 - \alpha_0 - \epsilon)$ approximate 1 under any conditions. Thus, equation (14) is preferable to equation (12) for determining geodetic latitude for any altitude.

However, even the smallest error in α_0 causes more than negligible error in the computation of h_s (eq. (11)), because the error is amplified by the scaling factor used to restore the true value of h after computations are completed. This analysis suggests that it is preferable to use the following exact formulas from reference 6 to compute h instead of equation (11):

$$x_{0} = \left[a/\left(1 - e^{2} \sin^{2} \varphi\right)^{1/2} + h \right] \cos \varphi \cos \lambda$$

$$y_{0} = \left[a/\left(1 - e^{2} \sin^{2} \varphi\right)^{1/2} + h \right] \cos \varphi \sin \lambda$$

$$z_{0} = \left[a\left(1 - e^{2}\right)/\left(1 - e^{2} \sin^{2} \varphi\right)^{1/2} + h \right] \sin \varphi$$

where f = (a - b)/a and $e^2 = 2f - f^2$. Since latitude and longitude are known, h can be computed directly and the proper equation can be chosen to compute h to avoid division by values close to zero.

In this way the geodetic coordinates ϕ , λ_w , and h are determined exactly both mathematically and computationally. Therefore, the computational accuracy of the method is the accuracy of the computer used.

CONCLUDING REMARKS

A mathematically exact method for computing geodetic coordinates from geocentric coordinates is derived. The computational accuracy achieved by using the method is as accurate as the computer used. The transformation provides a primary standard and makes possible the evaluation of any of the existing methods.
